Shrimp farming in New Caledonia

Monday, 1 October 2001

By Hervé Lucien-Brun

Successful, integrated industry provides export income, jobs

Tolerance to low temperatures led to the selection of *Penaeus stylirostris* as the exclusive farmed shrimp species in New Caledonia.

Right: Aerial view of SODACAL shrimp farm.

Shrimp farming in New Caledonia – a French Overseas Territory located in the Pacific Ocean about 2,500 km northeast of Brisbane, Australia – began in 1970 at the Saint Vincent Station and operated by the South Pacific Commission (CPS) and FAO. The New Caledonian Association for the Development of Aquaculture (AQUACAL) took over management of the Saint Vincent Station in 1973, and IFREMER became the scientific and technical director of the Association. The first small-scale shrimp farm (Ferme Chevallier) was established in 1981, and the first industrial farm (SODACAL) in 1983. The first shrimp meal factory (SICA) was set up in 1984, and the first private hatchery (SODACAL) hatchery and packing plant to export in 1988.

Production has grown steadily and reached around 2,000 tons in 1999. Currently, the shrimp-farming sector includes ten farms (450 ha of ponds), four hatcheries and two shrimp meal plants, (SICA and MSV), and one packing plant (SOPAC) that exports mainly to France, Japan and Australia. The industry is organized through a network into a professional association, the GFA (Groupement des Fermes Aquacoles de Nouvelle Calédonie). Shrimp farming has an important economic impact, through exports (currently the second most important export item) and by providing jobs in rural areas.

Lucien-Brun, Annual shrimp production, Table 1

Year	Production (mt)
1986	65
1987	87
1988	217
1989	296
1990	539
1991	648
1992	733
1993	632
1994	691
1995	878
1996	985
1997	1,107
1998	1,569
1999	1,906

Table 1. Annual shrimp production of New Caledonia farms.

Species, seedstock production

Initially it was necessary to select a shrimp species that would perform well under local climatologic conditions, but none of the local species produced adequate growth or survival. Eventually it was determined that the best species was a Mexican strain of *Penaeus stylirostris* brought in from Arizona. Since its introduction, shrimp farmers have produced their own broodstock and more than 30 generation have been produced in captivity, New Caledonia was one of the first countries to develop an industrial shrimp farming industry based on domesticated broodstock, and today, its growth performance is superior to that of the original strain. It also shows some specific IHHNV resistance. Hatcheries implement mostly AQUACOP techniques including artificial insemination. Some hatcheries use only microparticulated diets and artemia, and no microalgae.

Farms

Shrimp farm design in New Caledonia is adapted to its very irregular shoreline and to respect the environment (including mangroves) and avoid encroachment. All farms are located on the West coast and behind the mangrove area. Availability of suitable land was limited, so large farms – like those found in Latin America – have not developed. Seawater used has a high productivity that is reflected in pond natural production.

Existing farms can be classified into three types: three farms under 20 ha (8 percent of total area, 6 percent of total production), five farms from 20 to 50 ha (43 percent of total area, 48 percent of total production), and two farms with more than 50 ha (48 percent of total area, 47 percent of total production). Aerated ponds (44 percent of total area, 53 percent of total production) have an average area of 3.8 ha and non-aerated ponds average 8.5 ha. Sample production is shown in Table 2.

Lucien-Brun, Area and production, Table 2

Shrimp Farm	Pond Area (ha)	1999 Production (mt)
Aquamer	40.6	174.2
Aquamon	42.9	165.0
Bassns Dumbea	19.0	25.0
Blue Lagoon Farms	83.0	403.9
FAO	7.8	34.0
Peneide de Ouano	35.0	161.5
SASV	7.4	21.9
Sea Farm	34.2	127.9
SODACAL	129.0	564.6
Ferme Webuihoone	44.7	186.7
Ferme Tournier	11.0	41.2
Total	454.0	1,905.9

Table 2. Area and production of New Caledonia shrimp farms.

Seasonality

The industry is limited by the cool season. Most ponds are stocked only once. Most farmers keep their ponds dry during July and August, and restock in September. As a result, the relatively high production costs forced farmers to optimize pond production by increasing stocking density to 25 to 35 juveniles per square meter for aerated ponds, and 15 to 25 juvenile per square meter for non-aerated ponds. To maintain acceptable biomass (< 400 grams per square meter), partial harvests are done when animals reach 16 grams, with final harvests at 47 to 50 grams. In 2000, aerated ponds averaged 4.66 metric tons (MT) per hectare per cycle and non-aerated ponds 3.45 MT hectare per cycle.

The strong seasonality also increases fixed costs for hatcheries and packing plants. Hatcheries had to improve their productivity to provide all seedstock during a short period, between September and January. The packing plant had to modify its design and organization to increase from 10 to 16 MT of processed shrimp daily. This situation forces close integration of the industry at all levels, and every month the farmers and the packing plant manager schedule harvests with a maximum of four harvests of 4 MT each.

Processing, marketing

The first packing plant, owned by SODACAL, was initially established at the farm in 1988. In 1994, it was bought by SOPAC and relocated to Nouméa. In 1995, considering the increase of production and harvest seasonality, the plant was reorganized and expanded to conform to the norms of the main importer countries and be able to process 16 MT per day.

Most production is packed head-on, frozen in brine, and marketed in France (574 MT), Japan (310 MT) and Australia (264 MT), and also locally. Development of shrimp farming has boosted the local market. During the early 1980s, New Caledonians consumed only a few hundred kilograms per year, mostly wild-caught, small *P. merguensis*, but local demand has increased to over 490 MT per year.

Commercial strategy

Because of high production costs, New Caledonian shrimp products must be sold in top-quality markets. SOPAC markets all shrimp exports from New Caledonia, and has developed a strong commercial strategy that is profitable to farmers. SOPAC and the farmers have a list of specification defining all rearing and packing procedures, from the broodstock and seedstock production, to grow-out and harvest. This results in constant high quality and allows buyers to know the products well.

Quality certification

All industry members are involved in a process to obtain the internationally recognized "QUALICERT" label for quality products. Hatcheries must be certified for rearing procedures and sanitary conditions. Farms must comply with environmental rules, stock at no more than 40 juveniles per square meter, keep production at no more than 400 grams per square meter, and implement strictly defined harvest procedures and 30-day dry out of ponds between cycles.

Feed processors must be certified for types of ingredient, quality of raw materials, and sanitary conditions. Shrimp transporters are controlled from the sanitary condition of the trucks, the duration of the trip, and the temperature of the shrimp during transport. The packing plant complies with strict organoleptic controls and sanitary standards, and rejects non-conforming shrimp. An active quality-control team organized with the veterinarian authorities oversees the bacteriological controls.

Because of the industry's importance to the local economy, the Economic Observatory of the Shrimp Farming Sector (OEFA) was established to provide technical and economic analysis of shrimp farming in the sector to improve results as much as possible. It is directed by a board that includes representatives of the North and South Provinces, the Direction of the Rural Economy, SOPAC, and the GFA under the Presidency of ERPA, a government agency that surveys the local economy. The GFA handles operational management of the OEFA. OEFA provides monthly reports with harvest results from the previous month, forecasts production, and analyses production costs.

Future development

Further industry development will continue in two ways. One is implementation of improved rearing technology, with IFREMER support in the areas of genetic improvement, immunology, pathology and others. The other is increased farming area. Several years ago IFREMER inventoried potential sites, and a current study will show an additional 1,000 ha could be developed, which could improve production to 5,000 MT in the next decade.

Conclusion

The New Caledonian shrimp aquaculture is a model of originality. Locally developed and implemented semi-intensive technology allows farmers to achieve very high yields in an environmentally friendly manner. The industry has integrated closely to produce top-quality export products well positioned in world markets. Further industry development could significantly increase production.
